

Eggs

A mother Frog lays thousands of eggs at a time. Most Frogs lay their eggs in a pond of water. The eggs float on the water in a jelly mass, cluster known as Frogspawn. These eggs hatch within 6 - 21 days, depending on the breed of Frog.

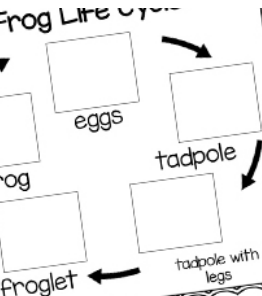

Frogs

Frogs begin their life in the water. They start as eggs, grow into tadpoles and then transform into Frogs and move onto fully land. They usually live anywhere from four to fifteen years.

Tadpoles

When the eggs hatch, a tadpole is born. This tadpole doesn't look at all like a Frog. It doesn't have legs and it has gills which it uses to breathe underwater. During the next four weeks, the tadpole swims, eats plants and algae and starts to develop lungs. After about 6-9 weeks after hatching, tiny hind legs start to sprout.

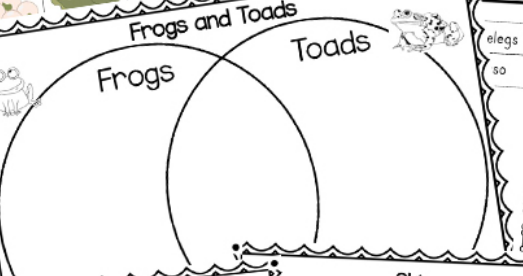

Predators

Common predators that feed on Frogs include snakes, lizards, birds and a variety of small animals. Even while swimming underwater, they have to watch out for some fish, swimming mammals and diving birds that could attack them.

Appearance

Frogs have two bulging eyes, and long, long webbed hind feet. These are used for leaping and swimming. Frogs have big round ears on the sides of their head call a tympanum.

Predators

Common predators that feed on Frogs include snakes, lizards, birds and a variety of small animals. Even while swimming underwater, they have to watch out for some fish, swimming mammals and diving birds that could attack them.

Swallowtail

Now, Frogs actually breathe through their skin. Frogs need to keep their skin moist, as they only get oxygen when it is moist. They do this by secreting a mucus as well as shed their skin regularly.
